

System Description :

The Career Networking Platform lets users create professional profiles, connect with other users, view companies, and apply for jobs. Companies can post job opportunities, and users can submit applications for those jobs. The database stores information about users, companies, jobs, connections, and job applications.

System Requirements :

The system must store user information and professional profiles. Users can connect with other users. Companies can create job postings. Each company can post multiple jobs. Users can apply for multiple jobs, and each job can receive multiple applications. The system must keep track of each application and its status.

Requirements Gathering Process :

The requirements were determined by researching how common career networking platforms work. The main features identified were professional profiles, networking connections, company profiles, job postings, and job applications. These features were then converted into entities and relationships for the database design.

Chen Style ER Diagram :

The Chen ER diagram represents the main entities and relationships of the Career Networking Platform. It shows how users connect with other users, companies post jobs, and users submit applications for jobs.

UML/EER Diagram :

The UML/EER diagram was created using MySQL Workbench. It contains the users, companies, jobs, applications, and connections tables. Primary keys and foreign keys are used to create relationships between the tables.

Conclusion :

This project demonstrates the design and creation of a database for a Career Networking Platform. The database allows users to create professional profiles, connect with other users, view companies, apply for jobs, and track job applications.
